

[Galaxy_TOC](#)

Text-XOR (TXOR)

TXOR is an encryption algorithm that differs from the [one-time pad](#) cipher only by a fact that in stead of using only 2 different values, the "true" and the "false", 1 and 0, {0,1}, the number of values that the TXOR uses can be any whole, finite, number that is greater than or equal to 2.

Motivation

The main motivation for developing the TXOR has been to use an encryption algorithm that has the security properties of the one-time pad, but that is computationally efficient to use within text processing oriented scripting languages like [PHP](#), [JavaScript](#), [Ruby](#).

The targeted use case of the TXOR is to use the maximum [Unicode](#) code value in stead of the classical "1" of the XOR based one-time pad.

As the range, $[0, \max(\text{Unicode codes})]$, contains numbers that have not been assigned to any existing character, cipher-texts can not be saved in text form without using some special encoding. For example, the cipher-text might be encoded as a comma-separated list of integers.

The Algorithm

$$\text{TXOR}(aa, bb, m) = ((bb - aa + m) \bmod m)$$

Prerequisites:

$$2 \leq m$$

$$0 \leq aa < m$$

$$0 \leq bb < m$$

The aa, bb, m are whole numbers.

The **bb** must always be in the role of a **key** and the **aa** must always be either in the role of a **clear-text** or in the role of a **cipher-text**.

An example:

$$\text{ciphertext} = \text{TXOR}(\text{cleartext}, \text{key}, m)$$

$$\text{cleartext} = \text{TXOR}(\text{ciphertext}, \text{key}, m)$$

Various Checks

Property h1

$$0 \leq (bb-aa+m)$$

According to prerequisites

$$\begin{aligned} 2 &\leq m \\ 0 &\leq aa < m \\ 0 &\leq bb < m \end{aligned}$$

Therefore the $(bb-aa)$ has its smallest value when $bb=0$ and $aa=(m-1)$.
 $0 \leq (bb-aa+m)$ because $0 \leq ((0-(m-1))+m)=1$

Property h2

$$\begin{aligned} 0 &\leq ((bb-aa+m) \bmod m) \\ &\text{id est} \\ 0 &\leq \text{TXOR}(aa,bb,m) \end{aligned}$$

According to the property h1 $0 \leq (bb-aa+m)$. According to the prerequisites ($0 < 2 \leq m$).
A remainder of a positive dividend and a positive [divisor](#) is a positive number.

Property h3

$$\begin{aligned} ((bb-aa+m) \bmod m) &< m \\ &\text{id est} \\ \text{TXOR}(aa,bb,m) &< m \end{aligned}$$

According to the property h2 and the prerequisites both, m and the $((bb-aa+m) \bmod m)$,
are positive numbers.

$((bb-aa+m) \bmod m)$ is a remainder of a division $((bb-aa+m) \bmod m)/m$.

If the dividend and the divisor are both positive numbers and the divisor is greater
than zero, then a remainder is always smaller than the divisor.

Property h4

$$\begin{aligned} 0 &\leq ((bb- ((bb-aa+m) \bmod m) +m) \bmod m) < m \\ &\text{and} \\ 0 &\leq (((((bb-aa+m) \bmod m) -aa+m) \bmod m) < m \\ &\text{id est} \end{aligned}$$

[Galaxy_TOC](#)

$$0 \leq \text{TXOR}(\text{TXOR}(\text{aa}, \text{bb}, m), \text{bb}, m) < m$$

and

$$0 \leq \text{TXOR}(\text{aa}, \text{TXOR}(\text{aa}, \text{bb}, m), m) < m$$

According to properties h2 and h3 $0 \leq \text{TXOR}(\text{aa}, \text{bb}, m) < m$
 Therefore, the $\text{TXOR}(\text{aa}, \text{bb}, m)$ is within the same bounds as the **aa** and the **bb**.
 and the same contemplation that showed that $0 \leq \text{TXOR}(\text{aa}, \text{bb}, m) < m$ applies for showing that

$$0 \leq \text{TXOR}(\text{TXOR}(\text{aa}, \text{bb}, m), \text{bb}, m) < m$$

and

$$0 \leq \text{TXOR}(\text{aa}, \text{TXOR}(\text{aa}, \text{bb}, m), m) < m$$

Property #1aa

$$\text{aa} = \text{TXOR}(\text{TXOR}(\text{aa}, \text{bb}, m), \text{bb}, m)$$

id est

If **bb** is a key and **aa** is the cleartext, then the decryption result always matches with the encrypted cleartext.

$$\text{ciphertext} = \text{TXOR}(\text{aa}, \text{bb}, m) = ((\text{bb} - \text{aa} + m) \bmod m)$$

$$\begin{aligned} \text{TXOR}(\text{TXOR}(\text{aa}, \text{bb}, m), \text{bb}, m) &= \text{TXOR}(\text{ciphertext}, \text{bb}, m) = ((\text{bb} - \text{ciphertext} + m) \bmod m) = \\ &= ((\text{bb} - ((\text{bb} - \text{aa} + m) \bmod m) + m) \bmod m) = g \end{aligned}$$

If aa = g, then the Property #1aa holds.

If the formula of the **g**, the
 $g = ((\text{bb} - \{ ((\text{bb} - \text{aa} + m) \bmod m) \} + m) \bmod m)$
 transforms to **aa**, then **aa = g** can be transformed to **aa = aa**
 and the condition **aa = g** is met.

$$\text{bb} - ((\text{bb} - \text{aa} + m) \bmod m) + m - g = c1 * m$$

$$\begin{aligned} -((\text{bb} - \text{aa} + m) \bmod m) &= c1 * m - m + g - \text{bb} \\ -((\text{bb} - \text{aa} + m) \bmod m) &= (c1 - 1) * m + g - \text{bb} \\ -((\text{bb} - \text{aa} + m) \bmod m) &= c2 * m + g - \text{bb} \end{aligned}$$

$$((\text{bb} - \text{aa} + m) \bmod m) = \text{bb} - g - c2 * m$$

$$\begin{aligned} (\text{bb} - \text{aa} + m) - (\text{bb} - g - c2 * m) &= c3 * m \\ \text{bb} - \text{aa} + m - \text{bb} + g + c2 * m &= c3 * m \\ -\text{aa} + g + (c2 + 1) * m &= c3 * m \\ -\text{aa} + g = c3 * m - (c2 + 1) * m \\ -\text{aa} + g &= c3 * m - c4 * m \\ -\text{aa} + g &= c5 * m \end{aligned}$$

$$\text{aa} = (g \bmod m)$$

According to the preconditions, $0 \leq \text{aa} < m$ and
 according property h4 $0 \leq g < m$.
 Therefore, **g = aa**.

Q.E.D.

Property #1bb

[Galaxy_TOC](#)

Generally $bb = TXOR(aa, TXOR(aa, bb, m), m)$ does not hold.
id est

If aa is a key and bb is the cleartext, then the decryption result might not match with the encrypted cleartext.

$bb = TXOR(aa, TXOR(aa, bb, m), m)$ can be shown to be false by finding one example, where it is false.

The example values are:

$$aa = key = 2$$

$$bb = clear-text = 6$$

$$m = 10$$

$$\text{ciphertext} = TXOR(aa, bb, m) = ((bb - aa + m) \bmod m) = ((6 - 2 + 10) \bmod 10) = 14 \bmod 10 = 4$$

$$TXOR(aa, TXOR(aa, bb, m), m) = TXOR(aa, \text{ciphertext}, m) = \text{decryption-result} =$$

$$= ((\text{ciphertext} - aa + m) \bmod m) = ((4 - 2 + 10) \bmod 10) = (12 \bmod 10) = 2$$

$$2 \neq 4$$

Q.E.D.

Property #2com

In respect to aa and bb the $T XOR(aa, bb, m)$ is not [commutative](#).

id est

There exist cases, where $T XOR(x, y, m) \neq T XOR(y, x, m)$

Sample values:

$$x=2, y=6, m=10$$

$$T XOR(x, y, m) = (y - x + m) \bmod m = ((6 - 2 + 10) \bmod 10) = 4$$

$$T XOR(y, x, m) = (x - y + m) \bmod m = ((2 - 6 + 10) \bmod 10) = 6$$

$$4 \neq 6$$

Q.E.D.

That is to say that

$$XOR(x, y) = XOR(y, x)$$

but

$$T XOR(x, y, m) \neq T XOR(y, x, m)$$

Property #3stat

Galaxy_19c If cleartext is a constant, then ciphertexts of different keys never collide.

id est

If $bb_1 \neq bb_2$, then $TXOR(aa, bb_1, m) \neq TXOR(aa, bb_2, m)$

$$TXOR(aa, bb_1, m) = ((bb_1 - aa + m) \bmod m) = ((bb_1 + c_1) \bmod m)$$

$$TXOR(aa, bb_2, m) = ((bb_2 - aa + m) \bmod m) = ((bb_2 + c_1) \bmod m)$$

Due to the "mod m" part of the equations the $((bb_1 + c_1) \bmod m)$ equals with the $((bb_2 + c_1) \bmod m)$ only, if $bb_1 = bb_2 + c_2 * m$. Due to one of the prerequisites, the $(0 \leq bb < m)$, the $c_2 = 0$, because otherwise $m \leq bb_2$, which would violate the prerequisite.

If the $TXOR(aa, bb_1, m) = TXOR(aa, bb_2, m)$ only, when the $bb_1 = bb_2$, then $TXOR(aa, bb_1, m) \neq TXOR(aa, bb_2, m)$, whenever $bb_1 \neq bb_2$.

Q.E.D.

Consequently, for any clear-text value there exists as many possible ciphertext values as there are values in the key-space, $(0 \leq bb < m)$, number of possible keys is $(m-1)$, and the same kind of [unbreakability proof](#) applies as is used for the one-time pad.

Historical Notes

I martin.vahi@softf1.com, first published the TXOR idea as a comment at minut.ee sometime before the year 2013.

This, relatively cleanly written, HTML version of the TXOR specification has been written in August 2013. The presented TXOR algorithm is probably nothing new or original, but I figured it out myself by extending the classical one-time pad by utilising the classical modulo arithmetic.

As free advertisement is always beneficial to freelancers like me and it had happened to me before that a simplistic, self-figured-out, algorithm turned out to be totally unique, I link a signed (read: timestamped) [version of this document](#) into itself.

2021_12_31 comment: In 2013_08 I received some very nice [feedback on LWN.net\(2021_12_31_archival_copy\)](#). Part of the criticism seems to be that with symmetric key crypto-algorithms it is so difficult to exchange keys that symmetric key crypto-algorithms are seen as impractical for web applications. Another part of the criticism seems to be that the conversion between character codes, whole numbers, and character encoding bitstreams seems to be so difficult to avoid that an encryption algorithm that is specifically designed to work with whole numbers does not offer enough benefits from speed/efficiency point of view. It might be that I misunderstood the feedback that I received.

Thank You for reading this HTML-page. :-)
